

# Advanced Java

*Trainer: Nilesh Ghule*

# Movie Review Assignment

# JSP = Java Server Pages

JSP is outdated.

Servlet = Business Logic + Presentation Logic

JSP = Presentation Logic + Business Logic  
↳ markup (tags)                      ↳ Java

JSP is converted into Servlets while execution.  
Ideal JSP doesn't have any Java code in it.

JSP Syntax → HTML and other tags +

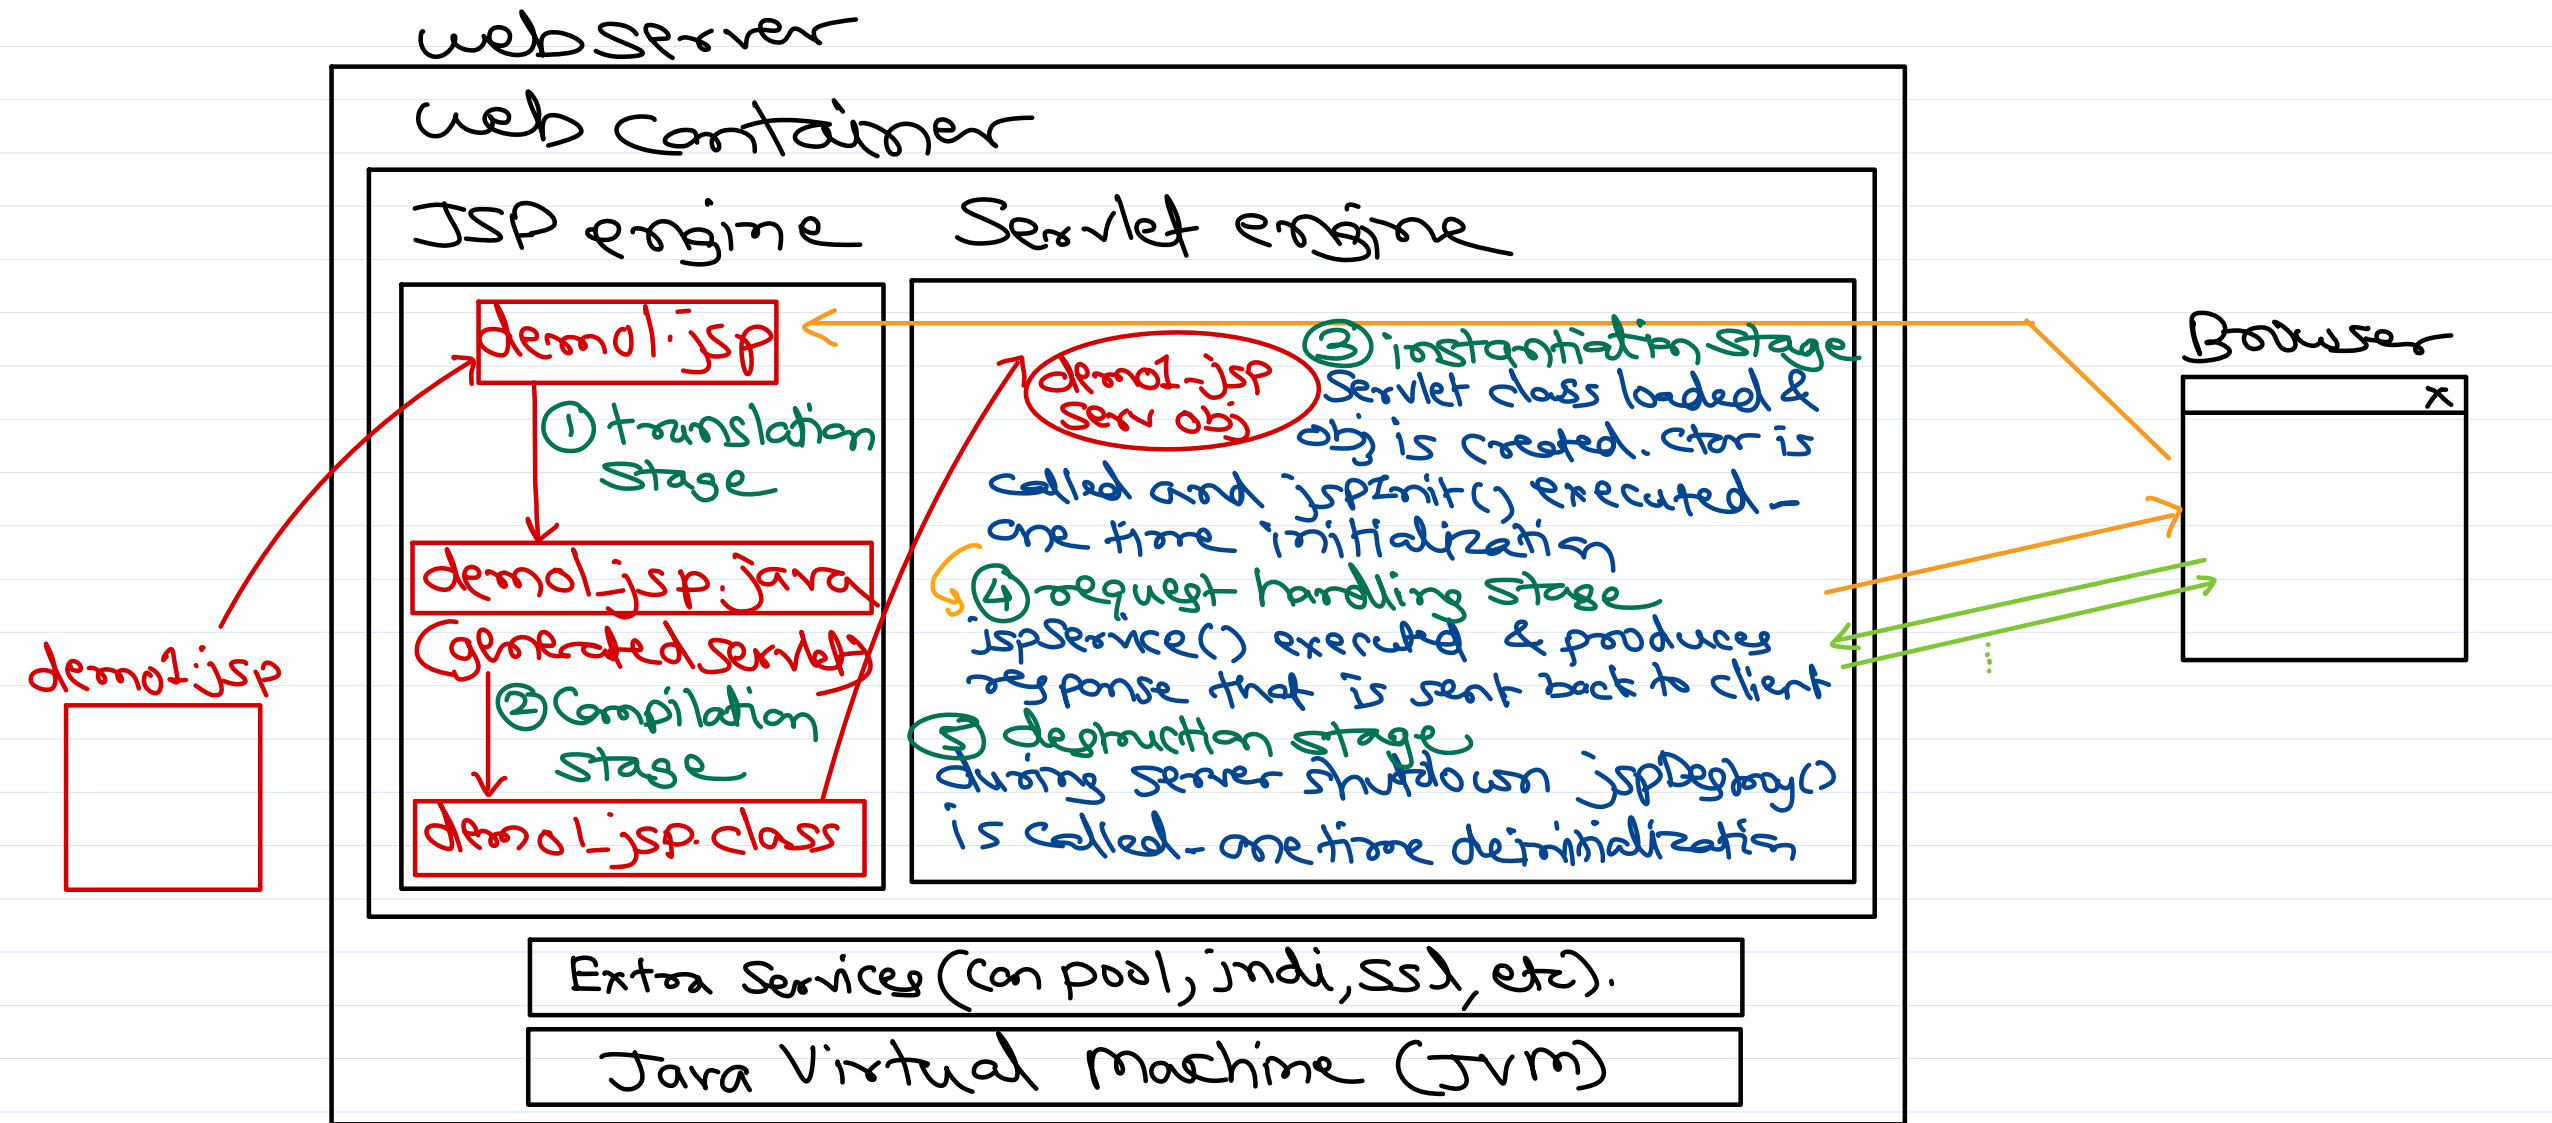

- ① Directive: `<%@ ... %>` } instructions to convert JSP into the servlet class.
- ② Declaration: `<%! ... %>` } become part of generated servlet class
- ③ Scriptlet: `<% ... %>` } become part of `jspService()` & executed per req.
- ④ Expression: `<%= ... %>` }
- ⑤ Comment: `<%-- ... --%>` } discarded during servlet conversion.

→ `jspService()` executed per request. It has few local variables a.k.a. JSP Implicit Objects.

- ① request: `HttpServletRequest`
- ② response: `HttpServletResponse`
- ③ session: `HttpSession`
- ④ config: `ServletConfig`
- ⑤ application: `ServletContext`
- ⑥ page: `Object` (this - JSP/serv obj)
- ⑦ out: `JspWriter` (like `PrintWriter`)
- ⑧ `pageContext`: `PageContext` (obj that holds all objs needed for executing JSP and storing page attributes).
- ⑨ exception: `Throwable` (obj to represent exception in error JSP pages).

# JSP Life Cycle

# JSP syntax

① directives `<%@ ... %>`

- page → JSP behavior/setting/config
- include → include another page
- taglib → using third party tags (Spring JSTL)

⑤ `<!-- Comment -->`

② declaration

`<%! ... %>` → JSP class fields & methods.

③ **Scriptlet**

`<% ..... java code ... %>`

**executed per request**

④ **Expression**

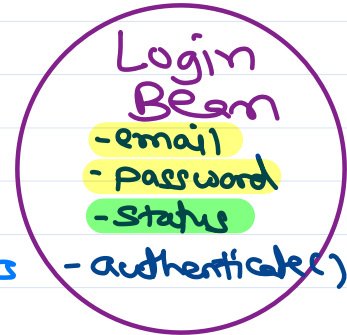

`<%= java expr %>` → output is added to response.

# JSP & Java Beans

## Java Bean Scopes

- ① page : PageContext attrs
- ② request : ServletRequest attrs
- ③ session : HttpSession attrs
- ④ application : ServletContext attrs

demo 05.jsp

email:

password:

login.jsp

```
if (status)
    welcome
else
    Failed
```

## JSP:useBean internals

```
lb = pageContext.getAttribute("lb");
if (lb == null) {
    lb = new LoginBean();
    pageContext.setAttribute("lb", lb);
}
```

3

① To create JavaBean and add in scope:

```
<jsp:useBean id="lb" class="pkg.LoginBean" scope="Page" />
```

② To set bean fields (by req param or fixed value).

```
<jsp:setProperty name="lb" property="password"
    param="passwd" />
```

internally calls setter method ← field/property name  
internally calls req.getParameter("...") ← req param name

```
<jsp:setProperty name="lb" property="*" />
```

auto set all properties/fields of given bean whose name is matching with req parameter.

```
<jsp:setProperty name="lb" property="fieldName"
    value="someValue" />
```

initialize given field with given value.

③ To get bean field value & display in output.

```
<jsp:getProperty name="lb" property="email" />
```

internally call getter method

④ To execute bean business logic method.

```
<% lb.authenticate(); %>
```

*Thank you!*
